FIBRICOR™ (FENOFIBRIC ACID): THE SENSIBLE ALTERNATIVE TO TRICOR® AND TRILIPIX®*

Dear Pharmacist:

At a time when patients are struggling with economic challenges, FIBRICOR is a low-cost alternative to TriCor or TriLipix.*

Generic (fenofibric acid) tablets are now available!

With the introduction of fenofibric acid tablets, the authorized generic for FIBRICOR, most patients can have their FIBRICOR prescription filled affordably with a generic at a Tier-1 copay.

When should you dispense fenofibric acid?

1. Fenofibric acid tablets should be dispensed as the generic for FIBRICOR prescriptions.
2. For patients prescribed TriCor or TriLipix, please let them know that there is a low-cost alternative available, often with a Tier-1 copay,† and suggest that they contact their doctor to prescribe FIBRICOR.
3. For patients prescribed TriCor or TriLipix, we also kindly ask you to assist them in contacting their doctor to suggest a cost-savings prescription for FIBRICOR.

FIBRICOR: An alternative to TriCor and TriLipix*

- FIBRICOR and TriCor are bioequivalent under fasted conditions and following a standard meal‡[1]
- Like TriCor and TriLipix, FIBRICOR can be taken without regard to meals[2-4]
- Fenofibric acid, the active ingredient of FIBRICOR, is the same active ingredient found in TriLipix§[2,3]

*FIBRICOR is not AB-rated to TriCor or TriLipix.

†Copays are determined by the patient's pharmacy benefit insurance carrier.

‡Following oral administration of FIBRICOR (105 mg) or TriCor (145 mg) in healthy volunteers, mean peak plasma levels of fenofibric acid occurred approximately 2.5 hours after administration. FIBRICOR was bioequivalent to TriCor in terms of rate and extent of absorption under fasted conditions and following a standard breakfast meal consisting of 36% fat and 575 kcal.[1]

§Fenofibric acid is the only pharmacologically active moiety following administration of TriLipix.[3]

FIBRICOR 105 mg 35 mg
(fenofibric acid) tablets

A switch to generic (fenofibric acid) tablets can save patients money!

For easy reference, the strengths and NDC numbers for both FIBRICOR™ and the low-cost generic-equivalent (fenofibric acid) tablets are listed below:

Description	Strength	Fill Size	NDC
Brand: FIBRICOR	105 mg	30	13310-102-07
		90	13310-102-90
	35 mg	30	13310-101-07
Authorized generic: fenofibric acid (Mutual)	105 mg	30	53489-678-07
		90	53489-678-90
	35 mg	30	53489-677-07

To learn more about FIBRICOR and fenofibric acid tablets, please refer to the attached sales brochure and visit www.fibricor.com/info or call 1.866.415.7675.

Kindest regards,

Gregory K. Hayer

Gregory K. Hayer
Sr. VP of Sales

FIBRICOR is a peroxisome proliferator receptor alpha (PPARα) activator indicated:

- To reduce triglyceride (TG) levels in patients with severe hypertriglyceridemia (≥ 500 mg/dl)
- To reduce elevated total cholesterol (TC), low-density-lipoprotein cholesterol (LDL-C), TG and apolipoprotein (Apo) B and to increase high-density lipoprotein cholesterol (HDL-C) in patients with primary hyperlipidemia or mixed dyslipidemia

IMPORTANT SAFETY INFORMATION

FIBRICOR is contraindicated in patients with severe renal impairment including those on dialysis, with active liver disease including primary biliary cirrhosis and unexplained persistent liver function abnormalities and with gallbladder disease. FIBRICOR is also contraindicated in nursing mothers and patients with hypersensitivity to fenofibric acid, choline fenofibrate or fenofibrate.

The most commonly reported adverse reactions (> 2% and greater than placebo) are increases in liver test values, abdominal pain, back pain, and headache.

Fenofibrate can increase serum transaminases, so patients should be monitored for AST or ALT changes periodically for the duration of the therapy. In addition, myopathy and rhabdomyolysis have been reported in patients taking fenofibrate. The risks of myopathy and rhabdomyolysis may be increased in patients who are elderly, have diabetes, renal failure, or hypothyroidism. Patients should be advised to report unexplained muscle pain, tenderness or weakness promptly, especially if accompanied by malaise or fever. Creatine phosphokinase (CPK) levels should be assessed in these patients. Fenofibrate can reversibly increase serum creatinine levels. Patients with renal impairment and those at risk for renal insufficiency should be periodically monitored. Fenofibrate increases cholesterol excretion into the bile, leading to risk of cholelithiasis. If cholelithiasis is suspected, gallbladder studies are indicated.

You are encouraged to report negative side effects of prescription drugs to the FDA. Visit www.fda.gov/medwatch or call 1-800-FDA-1088.

FENOFIBRIC ACID TABLETS

HIGHLIGHTS OF PRESCRIBING INFORMATION
These highlights do not include all the information needed to use fenofibric acid tablets safely and effectively. See full prescribing information for fenofibric acid tablets.

Fenofibric Acid Tablets
Initial U.S. Approval: 2009

---------- INDICATIONS AND USAGE ----------
Fenofibric acid tablets are a peroxisome proliferator receptor alpha (PPARα) activator indicated:

- To reduce triglyceride (TG) levels in patients with severe hypertriglyceridemia (≥ 500 mg/dl) (1.1).
- To reduce elevated total cholesterol (TC), low-density-lipoprotein cholesterol (LDL-C), TG and apolipoprotein (Apo) B and to increase high-density lipoprotein cholesterol (HDL-C) in patients with primary hyperlipidemia or mixed dyslipidemia (1.2).

General Considerations for Treatment: The active moiety of fenofibric acid tablets is fenofibric acid. The pharmacological effects of fenofibric acid have been extensively studied through oral administration of fenofibrate, which is converted *in vivo* to fenofibric acid (1.3).

Limitations of use: Fenofibrate as a dose equivalent to 105 mg of fenofibric acid tablets was not shown to reduce coronary heart disease morbidity and mortality in a large, randomized controlled trial of patients with type 2 diabetes mellitus (1.3).

---------- DOSAGE AND ADMINISTRATION ----------
- Fenofibric acid tablets may be taken without regards to meals (2.1).
- Severe hypertriglyceridemia: 35 to 105 mg/day; the dose should be adjusted according to patient response (2.2).
- Primary hyperlipidemia or mixed dyslipidemia: 105 mg/day (2.2).

---------- DOSAGE FORMS AND STRENGTHS ----------
Tablets: 35 mg and 105 mg (3)

---------- CONTRAINDICATIONS ----------
- Severe renal dysfunction, including patients receiving dialysis (4)
- Active liver disease (4)
- Gallbladder disease (4)
- Nursing Mothers (4)
- Known hypersensitivity to fenofibric acid or fenofibrate (4)

---------- WARNINGS AND PRECAUTIONS ----------
- Fenofibrate can increase serum transaminases. Monitor liver tests periodically (5.1).
- Fenofibrate increases cholesterol excretion into the bile, leading to risk of cholelithiasis. If cholelithiasis is suspected, gallbladder studies are indicated (5.2).
- Exercise caution in concomitant treatment with oral coumarin anticoagulants. Adjust the dosage of coumarin anticoagulant to maintain the prothrombin time/INR at the desired level to prevent bleeding complications (5.3).
- Myopathy and rhabdomyolysis have been reported in patients taking fenofibrate. The risks of myopathy and rhabdomyolysis appears to be increased in elderly patients and patients with diabetes, renal failure, or hypothyroidism (5.4).
- Fenofibrate can reversibly increase serum creatinine levels. Monitor renal function periodically in patients with renal insufficiency (5.5).

---------- ADVERSE REACTIONS ----------
Most common adverse reactions (> 2% and greater than placebo) are increased liver tests, abdominal pain, back pain, and headache (6).

To report SUSPECTED ADVERSE REACTIONS, contact Mutual Pharmaceutical Company, Inc. at 1-888-351-3786 or FDA at 1-800-FDA-1088 or *www.fda.gov/medwatch*.

---------- DRUG INTERACTIONS ----------
- Oral Anticoagulants (7.1)
- Bile-Acid Binding Resins (7.2)
- Immunosuppressants (7.3)

---------- USE IN SPECIFIC POPULATIONS ----------
- Pediatric use: The safety and effectiveness in pediatric patients have not been established (8.4).
- Geriatric use: Determine dose selection based on renal function (8.5).
- Renal impairment: Avoid in patients with severe renal impairment; dose reduction required in patients with mild to moderate renal impairment (8.6).
- Hepatic impairment: Fenofibric acid tablets have not been evaluated in patients with hepatic impairment (8.7).

Revised: 8/2009

FULL PRESCRIBING INFORMATION

1 INDICATIONS AND USAGE

1.1 Severe Hypertriglyceridemia
Fenofibric acid tablets are indicated as adjunctive therapy to diet for treatment of severe hypertriglyceridemia (≥ 500 mg/dl). Improving glycemic control in diabetic patients showing fasting chylomicronemia will usually obviate the need for pharmacologic intervention.

Levels of serum triglycerides > 1000 mg/dl may increase the risk of developing pancreatitis. The effect of fenofibric acid tablets on reducing this risk has not been studied.

1.2 Primary Hyperlipidemia or Mixed Dyslipidemia
Fenofibric acid tablets are indicated as adjunctive therapy to diet to reduce elevated LDL-C, Total-C, TG, and Apo B, and to increase HDL-C in patients with primary hypercholesterolemia or mixed dyslipidemia.

1.3 Considerations of Treatment
Fenofibrate at a dose equivalent to 105 mg of fenofibric acid tablets was not shown to reduce coronary heart disease morbidity and mortality in a large, randomized controlled trial of patients with type 2 diabetes mellitus [*see Warnings and Precautions (5.6)*].

The active moiety of fenofibric acid tablets is fenofibric acid. The pharmacological effects of fenofibric acid have been extensively studied through oral administration of fenofibrate, which is converted *in vivo* to fenofibric acid.

2 DOSAGE AND ADMINISTRATION

2.1 Dosing Information
Fenofibric acid tablets can be given without regard to meals.

Patients should be placed on an appropriate lipid-lowering diet before receiving fenofibric acid tablets, and should continue this diet during treatment with fenofibric acid.

Laboratory studies should be done to ascertain that the lipid levels are consistently abnormal before instituting fenofibric acid tablets therapy. Every attempt should be made to control serum lipids with appropriate diet, exercise, weight loss in obese patients, and control of any medical problems such as diabetes mellitus and hypothyroidism that are contributing to the lipid abnormalities. Medications known to exacerbate hypertriglyceridemia (beta blockers, thiazides, estrogens) should be discontinued or changed if possible prior to consideration of triglyceride-lowering drug therapy.

Periodic determination of serum lipids should be obtained during initial therapy in order to establish the lowest effective dose of fenofibric acid tablets. Therapy should be withdrawn in patients who do not have an adequate response after two months of treatment with the maximum recommended dose of 105 mg per day.

Consideration should be given to reducing the dosage of fenofibric acid tablets if lipid levels fall significantly below the targeted range.

2.2 Recommended Adult Dose
Severe Hypertriglyceridemia: The initial dose is 35 to 105 mg per day. Dosage should be individualized according to patient response, and should be adjusted if necessary following repeat lipid determinations at 4 to 8 week intervals.

Primary Hyperlipidemia or Mixed Dyslipidemia: The dose of fenofibric acid tablets is 105 mg per day.

The maximum dose of fenofibric acid tablets is 105 mg per day.

2.3 Renal Impairment
In patients with mild-to-moderate renal impairment, treatment with fenofibric acid tablets should be initiated at a dose of 35 mg/day, and increased only after evaluation of the effects on renal function and lipid levels at this dose. The use of fenofibric acid tablets should be avoided in patients with severe renal impairment [*see Use in Specific Populations (8.6)* and *Clinical Pharmacology (12.3)*].

2.4 Geriatric Patients
Dose selection for the elderly should be made on the basis of renal function [*see Use in Specific Populations (8.6)*].

3 DOSAGE FORMS AND STRENGTHS
- 35-mg: White, round tablets. Debossed "AR 787".
- 105-mg: White, modified oval tablets. Debossed "AR 788".

4 CONTRAINDICATIONS
Fenofibric acid tablets are contraindicated in patients with:

- severe renal impairment, including those receiving dialysis [*see Clinical Pharmacology (12.3)*].
- active liver disease, including those with primary biliary cirrhosis and unexplained persistent liver function abnormalities [*see Warnings and Precautions (5.3)*].
- preexisting gallbladder disease.
- known hypersensitivity to fenofibric acid or fenofibrate [*see Warnings and Precautions (5.9)*].
- fenofibric acid tablets are also contraindicated in nursing mothers [*see Use in Specific Populations (8.3)*].

5 WARNINGS AND PRECAUTIONS

5.1 Abnormal Liver Tests
Fenofibrate (administered over a range of doses with the higher dose equivalent to 105 mg fenofibric acid) has been associated with increases in serum transaminases [AST (SGOT) or ALT (SGPT)].

In a pooled analysis of 10 placebo-controlled trials, increases to > 3 times the upper limit of normal of ALT occurred in 5.3% of patients taking fenofibrate versus 1.1% of patients treated with placebo. The incidence of increases in transaminases observed with fenofibrate therapy may be dose related.

Chronic active hepatocellular and cholestatic hepatitis associated with fenofibrate therapy have been reported after exposures of weeks to several years. In extremely rare cases, cirrhosis has been reported in association with chronic active hepatitis.

Periodic monitoring of liver tests (e.g., ALT) should be performed for the duration of therapy with fenofibric acid tablets, and therapy discontinued if enzyme levels persist above three times the normal limit.

5.2 Cholelithiasis
Fenofibric acid tablets, like fenofibrate, clofibrate and gemfibrozil, may increase cholesterol excretion into the bile, leading to cholelithiasis. If cholelithiasis is suspected, gallbladder studies are indicated. Fenofibric acid tablets therapy should be discontinued if gallstones are found.

5.3 Concomitant Use with Oral Anticoagulants
Caution should be exercised when fenofibric acid tablets are given in conjunction with oral anticoagulants. Fenofibric acid tablets may potentiate the anticoagulant effects of these agents resulting in prolongation of the prothrombin time/INR. Frequent monitoring of prothrombin time/INR and dose adjustment of the anticoagulant are recommended until the prothrombin time/INR has stabilized in order to prevent bleeding complications [*see Drug Interactions (7.1)*].

5.4 Myopathy
Fibrates increase the risk for myopathy and have been associated with rhabdomyolysis. The risk for serious muscle toxicity appears to be increased in elderly patients and in patients with diabetes, renal failure, or hypothyroidism.

Data from observational studies suggest that the risk for rhabdomyolysis is increased when fibrates, in particular gemfibrozil, are co-administered with an HMG-CoA reductase inhibitor (statin).

Myopathy should be considered in any patient with diffuse myalgias, muscle tenderness or weakness, and/or marked elevations of creatine phosphokinase levels.

Patients should be advised to report promptly unexplained muscle pain, tenderness or weakness, particularly if accompanied by malaise or fever. CPK levels should be assessed in patients reporting these symptoms, and fenofibric acid tablets therapy should be discontinued if markedly elevated CPK levels occur or myopathy is diagnosed.

5.5 Elevated Serum Creatinine
Elevations in serum creatinine have been reported in patients on fenofibrate. These elevations tend to return to baseline following discontinuation of fenofibrate. The clinical significance of these observations is unknown. Renal monitoring should be considered for patients with renal impairment and for patients at risk for renal insufficiency, such as the elderly and patients with diabetes.

5.6 Coronary Heart Disease Morbidity and Mortality
The effect of fenofibric acid tablets on coronary heart disease morbidity and mortality and non-cardiovascular mortality has not been established.

The Fenofibrate Intervention and Event Lowering in Diabetes (FIELD) study was a 5 year randomized, placebo-controlled study of 9795 patients with type 2 diabetes mellitus treated with fenofibrate. Fenofibrate demonstrated a non-significant 11% relative reduction in the primary outcome of coronary heart disease events (hazard ratio [HR] 0.89, 95% CI 0.75–1.05, p=0.16) and a significant 11% reduction in the secondary outcome of total cardiovascular disease events (HR 0.89 [0.80–0.99], p=0.04). There was a non-significant 11% (HR 1.11 [0.95, 1.29], p=0.18) and 19% (HR 1.19 [0.90, 1.57], p=0.22) increase in total and coronary heart disease mortality, respectively, with fenofibrate as compared to placebo.

Because of chemical, pharmacological, and clinical similarities between fenofibrate, clofibrate, and gemfibrozil, the adverse findings in 4 large randomized, placebo-controlled clinical studies with these other fibrate drugs may also apply to fenofibric acid.

In the Coronary Drug Project, a large study of post myocardial infarction of patients treated for 5 years with clofibrate, there was no difference in mortality seen between the clofibrate group and the placebo group. There was however, a difference in the rate of cholelithiasis and cholecystitis requiring surgery between the two groups (3.0% vs. 1.8%).

In a study conducted by the World Health Organization (WHO), 5000 subjects without known coronary artery disease were treated with placebo or clofibrate for 5 years and followed for an additional one year. There was a statistically significant, higher age – adjusted all-cause mortality in the clofibrate group compared with the placebo group (5.70% vs. 3.96%, p<0.01). Excess mortality was due to a 33% increase in non-cardiovascular causes, including malignancy, post-cholecystectomy complications, and pancreatitis. This appeared to confirm the higher risk of gallbladder disease seen in clofibrate-treated patients studied in the Coronary Drug Project.

The Helsinki Heart Study was a large (n=4081) study of middle-aged men without a history of coronary artery disease. Subjects received either placebo or gemfibrozil for 5 years, with a 3.5 year open extension afterward. Total mortality was numerically higher in the gemfibrozil randomization group but did not achieve statistical significance (p=0.19, 95% confidence interval for relative risk = 0.91–1.64). Although cancer deaths trended higher in the gemfibrozil group (p=0.11), cancers (excluding basal cell carcinoma) were diagnosed with equal frequency in both study groups. Due to the limited size of the study, the relative risk of death from any cause was not shown to be different than that seen in the 9 year follow-up data from World Health Organization study (relative risk=1.29). Similarly, the numerical excess of gallbladder surgeries in the gemfibrozil group did not differ statistically from that observed in the WHO study.

A secondary prevention component of the Helsinki Heart Study enrolled middle-aged men excluded from the primary prevention study because of known or suspected coronary heart disease. Subjects received gemfibrozil or placebo for 5 years. Although cardiac deaths trended higher in the gemfibrozil group, this was not statistically significant (HR 2.2, 95% confidence interval: 0.94–5.05). The rate of gallbladder surgery was not statistically significant between study groups, but did trend higher in the gemfibrozil group, (1.9% vs. 0.3%, p=0.07). There was a statistically significant difference in the number of appendectomies in the gemfibrozil group (6/311 vs. 0/317, p=0.029).

5.7 Pancreatitis
Pancreatitis has been reported in patients taking fenofibrate. This occurrence may represent a failure of efficacy in patients with severe hypertriglyceridemia, a direct drug effect, or a secondary phenomenon mediated through biliary tract stone or sludge formation with obstruction of the common bile duct.

5.8 Venothromboembolic Disease
In the FIELD trial, pulmonary embolus (PE) and deep vein thrombosis (DVT) were observed at higher rates in the fenofibrate- than the placebo-treated group. Of 9,795 patients enrolled in FIELD, there were 4,900 in the placebo group and 4,875 in the fenofibrate group. For DVT, there were 48 events (1%) in the placebo group and 67 (1%) in the fenofibrate group (p=0.074); and for PE, there were 32 (0.7%) events in the placebo group and 53 (1%) in the fenofibrate group (p=0.022).

In the Coronary Drug Project, a higher proportion of the clofibrate group experienced definite or suspected fatal or nonfatal pulmonary embolism or thrombophlebitis than the placebo group (5.2% vs. 3.3% at five years; p<0.01).

5.9 Hypersensitivity Reactions
Acute hypersensitivity reactions including severe skin rashes such as Stevens-Johnson syndrome and toxic epidermal necrolysis requiring patient hospitalization and treatment with steroids have been reported in individuals treated with fenofibrate.

5.10 Hematological Changes
Mild-to-moderate hemoglobin, hematocrit, and white blood cell decreases have been observed in patients following initiation of fenofibrate therapy. Thrombocytopenia and agranulocytosis have been reported in individuals treated with fenofibrate. Periodic monitoring of red and white blood cell counts is recommended during the first 12 months of fenofibric acid tablets administration.

6 ADVERSE REACTIONS

6.1 Clinical Trial Experience
Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in clinical practice.

Adverse reactions reported by 2% or more of patients treated with fenofibrate (and greater than placebo) during the double-blind, placebo-controlled trials are listed in Table 1. Adverse reactions led to discontinuation of treatment in 5% of patients treated with fenofibrate and in 3% treated with placebo. Increases in liver tests were the most frequent events, causing discontinuation of fenofibrate treatment in 1.6% of patients.

Table 1. Adverse Reactions Reported by 2% or More of Patients Treated with Fenofibrate* During the Double-Blind, Placebo-Controlled Trials

BODY SYSTEM Adverse Reactions	Fenofibrate* (N=439)	Placebo (N=365)
BODY AS A WHOLE		
Abdominal Pain	4.6%	4.4%
Back Pain	3.4%	2.5%
Headache	3.2%	2.7%
DIGESTIVE		
Nausea	2.3%	1.9%
Constipation	2.1%	1.4%
METABOLIC AND NUTRITIONAL DISORDERS		
Abnormal Liver Tests	7.5%	1.4%
Increased ALT	3%	1.6%
Creatine Phosphokinase Increased	3%	1.4%
Increased AST	3.4%	0.5%
RESPIRATORY		
Respiratory Disorder	6.2%	5.5%
Rhinitis	2.3%	1.1%

* Fenofibric acid is the active moiety of fenofibrate; Fenofibrate dosage equivalent to 105 mg fenofibric acid.

6.2 Postmarketing Experience
The following adverse reactions have been identified during postapproval use of fenofibrate. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure: myalgia, rhabdomyolysis, increased creatinine phosphokinase, pancreatitis, increased alanine aminotranaminase, increased aspartate aminotranaminase, muscle spasm, acute renal failure, hepatitis, cirrhosis, nausea, abdominal pain, anemia, headache, arthralgia and asthenia.

7 DRUG INTERACTIONS

7.1 Oral Anticoagulants
Caution should be exercised when fenofibric acid tablets are given in conjunction with coumarin anticoagulants. Fenofibric acid tablets may potentiate the anticoagulant effect of these agents resulting in prolongation of the prothrombin time/INR. Frequent monitoring of prothrombin time/INR and dose adjustment of the oral anticoagulant are recommended until the prothrombin time/INR has stabilized in order to prevent bleeding complications [*see Warnings and Precautions (5.3)*].

7.2 Bile-Acid Binding Resins
Since bile-acid binding resins may bind other drugs given concurrently, patients should take fenofibric acid tablets at least 1 hour before or 4 to 6 hours after taking another drug.

7.3 Immunosuppressants
Immunosuppressant agents such as cyclosporine and tacrolimus can impair renal function. When immunosuppressants and other potentially nephrotoxic agents are co-administered with fenofibric acid tablets, the lowest effective dose of fenofibric acid tablets should be employed and renal function should be monitored.

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy
Pregnancy Category C: Safety in pregnant women has not been established. There are no adequate and well controlled studies of fenofibric acid tablets in pregnant women. Fenofibric acid tablets should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

In female rats given oral dietary doses of 15, 75, and 300 mg/kg/day of fenofibrate from 15 days prior to mating through weaning, maternal toxicity was observed at a dose that results in exposure to fenofibric acid that is 50 times that at the MRHD of fenofibric acid.

In pregnant rats given oral dietary doses of 14, 127, and 361 mg/kg/day from gestation day 6–15 during the period of organogenesis, adverse developmental findings were not observed at 14 mg/kg/day (a dose that results in exposure to fenofibric acid that is approximately twice that at the MRHD of fenofibric acid). At higher multiples of human doses evidence of maternal toxicity was observed.

In pregnant rabbits given oral gavage doses of 15, 150, and 300 mg/kg/day from gestation day 6–18 during the period of organogenesis and allowed to deliver, aborted litters were observed at 150 mg/kg/day (20 times that at the MRHD of fenofibric acid). No developmental findings were observed at 15 mg/kg/day (an exposure to fenofibric acid that is 7 times that at the MRHD of fenofibric acid).

In pregnant rats given oral dietary doses of 15, 75, and 300 mg/kg/day from gestation day 15 through lactation day 21 (weaning), maternal toxicity was observed at an exposure to fenofibric acid that is approximately 50 times that at the MRHD of fenofibric acid [*see Nonclinical Toxicology (13.1)*].

8.3 Nursing Mothers
Fenofibric acid tablets should not be used by nursing mothers. A decision should be made whether to discontinue nursing or to discontinue the drug [*see Contraindications (4)*].

8.4 Pediatric Use
Safety and effectiveness of fenofibric acid tablets in pediatric patients have not been established.

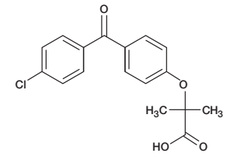
8.5 Geriatric Use
Fenofibric acid tablets are substantially excreted by the kidney as fenofibric acid and fenofibric acid glucuronide, and the risk of adverse reactions to this drug may be greater in patients with impaired renal function. Since elderly patients have a higher incidence of renal impairment, the dose selection for the elderly should be made on the basis of renal function [*see Dosage and Administration (2.3)* and *Clinical Pharmacology (12.3)*].

8.6 Renal Impairment
The use of fenofibric acid tablets should be avoided in patients who have severe renal impairment. Dose reduction is required in patients with mild-to-moderate renal impairment. Monitoring renal function in patients with renal impairment is recommended [*see Dosage and Administration (2.3)* and *Clinical Pharmacology (12.3)*].

8.7 Hepatic Impairment
The use of fenofibric acid tablets has not been evaluated in patients with hepatic impairment [*see Contraindications (4)*].

10 OVERDOSAGE
There is no specific treatment for overdose with fenofibric acid tablets. General supportive care of the patient is indicated, including monitoring of vital signs and observation of clinical status, should an overdose occur. If indicated, elimination of unabsorbed drug should be achieved by emesis or gastric lavage; usual precautions should be observed to maintain the airway. Because fenofibric acid is highly bound to plasma proteins, hemodialysis should not be considered.

11 DESCRIPTION
Fenofibric acid is a lipid regulating agent available as tablets for oral administration. Each tablet contains 35 mg or 105 mg of fenofibric acid. The chemical name for fenofibric acid is 2-[4-(4-chlorobenzoyl)phenoxy]-2-methylpropanoic acid with the following structural formula:



Fenofibric acid is a white to almost white crystalline powder that is stable under ordinary conditions, and has a melting point of 179 – 183°C. Its empirical formula is $C_{17}H_{15}ClO_4$ and molecular weight 318.75. Fenofibric acid is insoluble in water; its solubility increases with pH in buffered media.

Inactive Ingredients: Each tablet contains copovidone, crospovidone, magnesium stearate and microcrystalline cellulose.

12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action
The effects of fenofibric acid seen in clinical practice have been explained *in vivo* in transgenic mice and *in vitro* in human hepatocyte cultures by the activation of peroxisome proliferator activated receptor α (PPARα). Through this mechanism, fenofibric acid increases lipolysis and elimination of triglyceride-rich particles from plasma by activating lipoprotein lipase and reducing production of apoprotein C-III (an inhibitor of lipoprotein lipase activity). The resulting fall in triglycerides produces an alteration in the size and composition of LDL from small, dense particles to large buoyant particles. These larger particles have a greater affinity for cholesterol receptors and are catabolized rapidly. Activation of PPARα also induces an increase in the synthesis of apoproteins A-I, A-II and HDL-cholesterol.

12.2 Pharmacodynamics
Elevated levels of Total-C, LDL-C, and Apo B, and decreased levels of HDL-C and its transport complex, Apo AI and Apo AII, are risk factors for atherosclerosis. Epidemiologic studies have established that cardiovascular morbidity and mortality vary directly with the levels of Total-C, LDL-C, and TG, and inversely with the level of HDL-C. The independent effect of raising HDL-C or lowering TG on the risk of cardiovascular morbidity and mortality has not been determined.

12.3 Pharmacokinetics
Absorption
The absolute bioavailability of fenofibric acid tablets has not been determined. Following oral administration of fenofibric acid tablets in healthy volunteers, median peak plasma levels of fenofibric acid occur by approximately 2.5 hours after administration. Exposure after administration of 3 x 35 mg fenofibric acid tablets is comparable to 1 x 105 mg fenofibric acid tablets.

A food-effect study involving administration of fenofibric acid tablets to healthy volunteers under fasting conditions and with a high-fat meal indicated that the C_{max} was decreased by approximately 35% while the AUC remained unchanged. This decrease in exposure is not considered clinically significant, and therefore fenofibric acid tablets can be taken without regards to meals.

The extent and rate of absorption of fenofibric acid after administration of 105 mg fenofibric acid tablets are equivalent to those after administration of 145 mg fenofibrate tablets (TriCor®) under fasted conditions.

Distribution
Upon multiple dosing of fenofibrate, fenofibric acid steady state is achieved within 9 days. Plasma concentrations of fenofibric acid at steady state are slightly more than double those following a single dose. Serum protein binding was approximately 99% in normal and hyperlipidemic subjects.

Metabolism
Fenofibric acid is primarily conjugated with glucuronic acid and then excreted in urine. A small amount of fenofibric acid is reduced at the carbonyl moiety to a benzhydrol metabolite which is, in turn, conjugated with glucuronic acid and excreted in urine.

In vitro and *in vivo* metabolism data indicate that fenofibric acid does not undergo oxidative metabolism (e.g. cytochrome P450) to a significant extent. The enzymes CYP1A2, CYP2A6, CYP2B6, CYP2C8, CYP2C9, CYP2C19, CYP2D6, CYP2E1, and CYP3A4 do not play a role in the metabolism of fenofibric acid.

Elimination
Fenofibric acid is eliminated with a half-life of approximately 20 hours, allowing once-daily dosing.

Specific Populations
Geriatrics: In five elderly volunteers 77 – 87 years of age, the oral clearance of fenofibric acid following a single oral dose of fenofibrate was 1.2 L/h, which compares to 1.1 L/h in young adults. This indicates that an equivalent dose of fenofibric acid tablets can be used in elderly subjects with normal renal function, without increasing accumulation of the drug or metabolites [*see Use in Specific Populations (8.5)*].

Pediatrics: Fenofibric acid tablets have not been investigated in adequate and well-controlled trials in pediatric patients.

Gender: No pharmacokinetic difference between males and females has been observed for fenofibrate.

Race: The influence of race on the pharmacokinetics of fenofibric acid has not been studied, however fenofibric acid is not metabolized by enzymes known for exhibiting inter-ethnic variability.

Renal Impairment: The pharmacokinetics of fenofibric acid were examined in patients with mild, moderate, and severe renal impairment. Patients with severe renal impairment (creatinine clearance [CrCl ≤ 30 mL/min) showed a 2.7-fold increase in exposure for fenofibric acid and increased accumulation of fenofibric acid during chronic dosing compared to that of healthy subjects. Patients with mild (CrCl 50–80 mL/min) to-moderate (CrCl 30–50 mL/min) renal impairment had similar exposure but an increase in the half-life for fenofibric acid compared to that of healthy subjects. Based on these findings, the use of fenofibric acid should be avoided in patients who have severe renal impairment and dose reduction is required in patients with mild-to-moderate renal impairment.

Hepatic Impairment: No pharmacokinetic studies of fenofibric acid have been conducted in patients with hepatic impairment.

Drug-Drug Interactions: An *in vitro* study using human hepatocytes indicates that fenofibric acid does not induce CYP1A2, CYP2A6, CYP2B6, CYP2C9, CYP2C19, CYP2D6, CYP2E1, and CYP3A4.

In vitro studies using human liver microsomes indicate that fenofibric acid is not an inhibitor of cytochrome (CYP) P450 isoforms CYP3A4, CYP2D6, CYP2E1, or CYP1A2.

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

Carcinogenesis

Two dietary carcinogenicity studies have been conducted in rats with fenofibrate. In the first 24-month study, Wistar rats were dosed with fenofibrate at 10, 45, and 200 mg/kg/day, (approximately 0.3, 1, and 6 times the maximum recommended human (MRHD) dose on the basis of mg/sq meter surface area). At a dose of 200 mg/kg/day (6 times the MRHD), the incidence of liver carcinomas was significantly increased in both sexes. A statistically significant increase in pancreatic carcinomas was observed in males at 45, and 200 mg/kg/day (approximately 1, and 6 times the human dose on the basis of mg/sq meter surface area), an increase in pancreatic adenomas and benign testicular interstitial cell tumors was observed in males at a dose that results in exposure to fenofibric acid that is 6 times the human dose. In a second 24-month rat carcinogenicity study in a different strain of rats (Sprague-Dawley), doses of 10 and 60 mg/kg/day (1.2 and 16.5 times the MRHD of fenofibric acid, based upon exposure) produced significant increases in the incidence of pancreatic acinar adenomas in both sexes and increases in testicular interstitial cell tumors in males at 16.5 times the MRHD of fenofibrate (60 mg/kg/day).

A 117-week carcinogenicity study was conducted in rats comparing three drugs: fenofibrate 10 and 60 mg/kg/day (0.3 and 2 times the MRHD of fenofibrate), clofibrate (400 mg/kg/day; 2 times the human dose), and gemfibrozil (250 mg/kg/day; 2 times the human dose) (multiples based on mg/meter^2 surface area). Fenofibrate increased pancreatic acinar adenomas in both sexes. Clofibrate increased hepatocellular carcinoma and pancreatic acinar adenomas in males and hepatic neoplastic nodules in females. Gemfibrozil increased hepatic neoplastic nodules in males and females, while all three drugs increased testicular interstitial cell tumors in males.

In a 21-month study in CF-1 mice, fenofibrate 10, 45, and 200 mg/kg/day (approximately 0.2, 0.7, and 3 times the human dose on the basis of mg/sq meter surface area) significantly increased the liver carcinomas in both sexes at doses that result in exposure to fenofibric acid that is 3.7 times the MRHD of fenofibric acid. In a second 18-month study at 10, 60, and 200 mg/kg/day, fenofibrate significantly increased the liver carcinomas in male mice and liver adenomas in female mice at 3 times the MRHD of fenofibrate.

Electron microscopy studies have demonstrated peroxisomal proliferation following fenofibrate administration to the rat. An adequate study to test for peroxisome proliferation in humans has not been done, but changes in peroxisome morphology and numbers have been observed in humans after treatment with other members of the fibrate class when liver biopsies were compared before and after treatment in the same individual.

Mutagenesis

Fenofibrate has been demonstrated to be devoid of mutagenic potential in the following tests: Ames, mouse lymphoma, chromosomal aberration and unscheduled DNA synthesis in primary rat hepatocytes and *in vivo* in the mouse micronucleus assay.

Impairment of Fertility

In fertility studies, rats were given oral dietary doses of fenofibrate. Males received 61 days prior to mating and females 15 days prior to mating through weaning which resulted in no adverse effect on fertility at doses up to 300 mg/kg/day (approximately 10 times the MRHD of fenofibrate, based on mg/m^2 surface area comparisons).

14 CLINICAL STUDIES

14.1 Severe Hypertriglyceridemia

The effects of fenofibrate on serum triglycerides were studied in two randomized, double-blind, placebo-controlled clinical trials of 147 hypertriglyceridemic patients. Patients were treated for eight weeks under protocols that differed only in that one protocol entered patients with baseline triglyceride (TG) levels of 500 to 1500 mg/dL, and the other TG levels of 350 to 500 mg/dL.

In patients with hypertriglyceridemia and normal cholesterolemia with or without hyperchylomicronemia, treatment with fenofibrate at dosages equivalent to 105 mg of fenofibric acid tablets decreased primarily very low density lipoprotein (VLDL) triglycerides and VLDL cholesterol. Treatment of some with elevated triglycerides often results in an increase of low density lipoprotein (LDL) cholesterol (see Table 4).

Table 4: Effects of Fenofibrate in Patients with Elevated Triglycerides

Study 1	**Placebo**				**Fenofibrate**			
Baseline TG levels 350 to 499 mg/dL	N	Baseline (Mean)	Endpoint (Mean)	% Change (Mean)	N	Baseline (Mean)	Endpoint (Mean)	% Change (Mean)
Triglycerides	28	449	450	-0.5	27	432	223	-46.2*
VLDL Triglycerides	19	367	350	2.7	19	350	178	-44.1*
Total Cholesterol	28	255	261	2.8	27	252	227	-9.1*
HDL Cholesterol	28	35	36	4	27	34	40	19.6*
LDL Cholesterol	28	120	129	12	27	128	137	14.5
VLDL Cholesterol	27	99	99	5.8	27	92	46	-44.7*
Study 2	**Placebo**				**Fenofibrate**			
Baseline TG levels 500 to 1500 mg/dL	N	Baseline (Mean)	Endpoint (Mean)	% Change (Mean)	N	Baseline (Mean)	Endpoint (Mean)	% Change (Mean)
Triglycerides	44	710	750	7.2	48	726	308	-54.5*
VLDL Triglycerides	29	537	571	18.7	33	543	205	-50.6*
Total Cholesterol	44	272	271	0.4	48	261	223	-13.8*
HDL Cholesterol	44	27	28	5.0	48	30	36	22.9*
LDL Cholesterol	42	100	90	-4.2	45	103	131	45.0*
VLDL Cholesterol	42	137	142	11.0	45	126	54	-49.4*

* = $p < 0.05$ vs. Placebo

14.2 Primary Hyperlipidemia (Heterozygous Familial and Nonfamilial) and Mixed Dyslipidemia

The effects of fenofibrate at doses equivalent to 105 mg of fenofibric acid tablets were assessed from four randomized, placebo-controlled, double-blind, parallel-group studies including patients with the following mean baseline lipid values: Total-C 306.9 mg/dL; LDL-C 213.8 mg/dL; HDL-C 52.3 mg/dL; and triglycerides 191.0 mg/dL. Fenofibrate therapy lowered LDL-C, Total-C, and the LDL-C/HDL-C ratio. Fenofibrate therapy also lowered triglycerides and raised HDL-C (see Table 5).

Table 5. Mean Percent Change in Lipid Parameters at End of Fenofibrate Treatment†

Treatment Group	**Total-C**	**LDL-C**	**HDL-C**	**TG**
Pooled Cohort				
Mean baseline lipid values (n=646)	306.9 mg/dL	213.8 mg/dL	52.3 mg/dL	191.0 mg/dL
All FEN (n=361)	-18.7%*	-20.6%*	+11.0%*	-28.9%*
Placebo (n=285)	-0.4%	-2.2%	+0.7%	+7.7%
Baseline LDL-C >160 mg/dL and TG <150 mg/dL (Type IIa)				
Mean baseline lipid values (n=334)	307.7 mg/dL	227.7 mg/dL	58.1 mg/dL	101.7 mg/dL
All FEN (n=193)	-22.4%*	-31.4%*	+9.8%*	-23.5%*
Placebo (n=141)	+0.2%	-2.2%	+2.6%	+11.7%
Baseline LDL-C >160 mg/dL and TG ≥150 mg/dL (Type IIb)				
Mean baseline lipid values (n=242)	312.8 mg/dL	219.8 mg/dL	46.7 mg/dL	231.9 mg/dL
All FEN (n=126)	-16.8%*	-20.1%*	+14.6%*	-35.9%*
Placebo (n=116)	-3.0%	-6.6%	+2.3%	+0.9%

† Duration of study treatment was 3 to 6 months.
* $p = < 0.05$ vs. Placebo

In a subset of the subjects, measurement of Apo B was conducted. Fenofibrate treatment significantly reduced Apo B from baseline to endpoint as compared with placebo (-25.1% vs. 2.4%, $p < 0.0001$, n=213 and 143 respectively).

16 HOW SUPPLIED/STORAGE AND HANDLING

Fenofibric acid tablets 35 mg, are white, round tablets, debossed “AR 787” on one side and blank on the other side.

Bottles of 30 NDC 53489-677-07

Fenofibric acid tablets 105 mg, are white, modified oval tablets, debossed “AR 788” on one side and blank on the other side.

Bottles of 30 NDC 53489-678-07
Bottles of 90 NDC 53489-678-90

Store at 20° to 25°C (68° to 77°F).

[See USP Controlled Room Temperature]

DISPENSE IN TIGHT, LIGHT-RESISTANT CONTAINER.

17 PATIENT COUNSELING INFORMATION

Patients should be advised:

- of the potential benefits and risks of fenofibric acid tablets [*see Clinical Studies (14); Contraindications (4); Warnings and Precautions (5); Adverse Reactions (6)*].
- of medications that should not be taken in combination with fenofibric acid tablets [*see Drug Interactions (7)*].
- to continue to follow an appropriate lipid-modifying diet while taking fenofibric acid tablets [*see Dosing Information (2.1)*].
- to take fenofibric acid tablets once daily, without regard to food, at the prescribed dose [*see Dosage and Administration (2)*].
- to inform their physician of all medications, supplements, and herbal preparations they are taking and any change to their medical condition. Patients should also be advised to inform their physicians prescribing a new medication that they are taking fenofibric acid tablets.
- to inform their physician of any muscle pain, tenderness, or weakness; onset of abdominal pain; or any other new symptoms [*see Myopathy (5.4)*].
